

Presentation of right-angled Soergel categories by generators and relations

Nicolas Libedinsky

October 14, 2008

Abstract

Soergel bimodule category $\mathbf{B}$ is a categorification of the Hecke algebra of a Coxeter system $(W, \mathcal{S})$. We find a presentation of $\mathbf{B}$ (as a tensor category) by generators and relations when W is a right-angled Coxeter group.

1 Introduction

In 1979 [KL1], Kazhdan and Lusztig defined the Kazhdan-Lusztig polynomials, and this gave rise to what now is known as the Kazhdan-Lusztig theory. They stated two major conjectures involving these polynomials in [KL1] and [KL2] : Kazhdan-Lusztig conjecture (in representation theory of Lie algebras) and Kazhdan-Lusztig positivity conjecture (in algebraic combinatorics). The first conjecture was proved for Weyl groups by Beilinson and Bernstein in [BB], by Brylinski and Kashiwara in [BK] and later by Soergel [So1]. The second conjecture has been proved for Weyl or affine Weyl groups in [KL2] and in some other cases by Haddad [Had] and Dyer [Dy1].

In 1980 [Lu1], Lusztig stated a central conjecture in representation theory, known as Lusztig conjecture. This conjecture is about the characters values of the irreducible representations of algebraic groups in positive characteristic. This conjecture is solved only for large characteristics.

Let us consider $(W, \mathcal{S})$ a Coxeter system and $\mathcal{H}$ its Hecke algebra. In 1992 [So2], Soergel categorified $\mathcal{H}$. This means that he defined a tensor category $\mathbf{B}$ (that depends on a field k and on a representation of W) and an isomorphism of rings $\mathcal{E}$ from $\mathcal{H}$ to the split Grothendieck group of $\mathbf{B}$. He has then stated a conjecture that links, via $\mathcal{E}$, the Kazhdan-Lusztig basis elements in $\mathcal{H}$ with the indecomposable elements of $\mathbf{B}$. This conjecture implies Kazhdan-Lusztig

positivity conjecture, and when the characteristic of k is larger than the coxeter number h of W , it implies a part of Lusztig conjecture.

Soergel introduced this category in the case of Weyl groups to make a link between the BGG category $\mathcal{O}$ of a semisimple complex Lie algebra and the perverse sheaves over the grassmanians. This link with geometry allowed him to prove his conjecture in the Weyl group case. He deduced in [So1] the proof of Kazhdan-Lusztig conjecture we have mentioned.

The following diagram is a summary of the implications

In this paper, we are concerned with the case where $(W, \mathcal{S})$ is a right-angled Coxeter system. This means that $m(s, r) = 2$ or ∞ for all $s, r \in \mathcal{S}$. In this case, we find a presentation as tensor category of $\mathbf{B}$ (called right-angled Soergel category) by generators and relations. Our main motivation to do this is the following. If we can extend this result to any Coxeter system we expect to be able to do the following : to reprove Kazhdan-Lusztig conjecture in the spirit of [So1] but (from our perspective) in a more natural way and to reprove a part of Lusztig conjecture (comparison between quantum group and algebraic group) in an essentially different way than the proof in [AJS].

To extend the result of this paper to the symmetric group would be a step forward in the program of calculating Khovanov-Rozansky link homology (a categorification of the HOMFLYPT polynomial) defined in [Kh] via Soergel category $\mathbf{B}$. Some results in this direction are given in the papers [Ra] and [WW].

We should say that the right-angled case is very rich in topological and geometrical terms. For example, in the introduction of [Da] Davis remarks that the right-angled case is sufficient for the construction of most examples of interest in geometric group theory.

This paper is divided as follows: in sections 2 and 3 we have the basic definitions and preliminaries. From section 4 to section 10 we prove the central theorem 3.1. At the beginning of section 4 we make a summary of the proof.

2 Notations and preliminaries

2.1 Basic definitions

Let $(W, \mathcal{S})$ be a not necessarily finite Coxeter system (with $\mathcal{S}$ a finite set) and $\mathcal{T} \subset W$ the set of reflections in W , *i.e.* the orbit of $\mathcal{S}$ under conjugation. Let k be an infinite field of characteristic different from 2 and V a finite dimensional k -representation of W . For $w \in W$, we denote by $V^w \subset V$ the set of w -fixed points. The following definition might be found in [So4] :

Definition By a *reflection faithful representation* of $(W, \mathcal{S})$ we mean a faithful, finite dimensional representation V of W such that, for each $w \in W$, the subspace V^w is an hyperplane of V if and only if $w \in \mathcal{T}$.

From now on, we consider V a reflection faithful representation of W . If $k = \mathbb{R}$, by the results of [Li2], all the results in this paper will stay true if we consider V to be the geometric representation of W (still if this representation is not always reflection faithful).

Let $\hat{R} = R(V)$ be the algebra of regular functions on V . The action of W on V induces an action on $\hat{R}$. For $s \in \mathcal{S}$ consider the $(\hat{R}, \hat{R})$ -bimodule $\hat{\theta}_s = \hat{R} \otimes_{\hat{R}^s} \hat{R}$, where $\hat{R}^s$ is the subspace of $\hat{R}$ stabilized by s .

Definition Soergel's category $\mathbf{B}(W, V) = \mathbf{B}$ is the full subcategory of all $(\hat{R}, \hat{R})$ -bimodules with objects the finite direct sums of direct summands of bimodules of the type $\hat{\theta}_{s_1} \otimes_{\hat{R}} \hat{\theta}_{s_2} \otimes_{\hat{R}} \cdots \otimes_{\hat{R}} \hat{\theta}_{s_n}$ for $(s_1, \dots, s_n) \in \mathcal{S}^n$.

For simplicity, we will denote by $\hat{\theta}_{s_1} \hat{\theta}_{s_2} \cdots \hat{\theta}_{s_n}$ the $(\hat{R}, \hat{R})$ -bimodule $\hat{\theta}_{s_1} \otimes_{\hat{R}} \hat{\theta}_{s_2} \otimes_{\hat{R}} \cdots \otimes_{\hat{R}} \hat{\theta}_{s_n} \cong \hat{R} \otimes_{\hat{R}^{s_1}} \hat{R} \otimes_{\hat{R}^{s_2}} \cdots \otimes_{\hat{R}^{s_n}} \hat{R}$

More details about this category can be found in the papers by Dyer [Dy2], [Dy3], by Fiebig [Fie1], [Fie2], [Fie3], by myself [Li1], [Li2], by Soergel [So1], [So2], [So3], [So4] and by Williamson [Wi], being [So4] the central and more complete reference from our point of view.

We will use an auxiliary subcategory of $\mathbf{B}$, where we do not consider the direct summands :

Definition $\hat{\mathbf{B}}$ is the full subcategory of $\mathbf{B}$ with objects the finite direct sums of bimodules of the type $\hat{\theta}_{s_1} \hat{\theta}_{s_2} \cdots \hat{\theta}_{s_n}$ for $(s_1, \dots, s_n) \in \mathcal{S}^n$.

2.2 Stability of V'

Let $\hat{x}_s \in V^*$ be an equation of the hyperplane H_s fixed by $s \in \mathcal{S}$. We have a decomposition $\hat{R} \simeq \hat{R}^s \oplus \hat{x}_s \hat{R}^s$, corresponding to

$$\hat{R} \ni p = \frac{p + s \cdot p}{2} + \frac{p - s \cdot p}{2}.$$

We define $\hat{P}_s(p) = (p + s \cdot p)/2$, $\hat{I}_s(p) = (p - s \cdot p)/2$ and $\hat{\partial}_s(p) = (p - s \cdot p)/2\hat{x}_s$. As W acts trivially over

$$(\sum_{s \in \mathcal{S}} k\hat{x}_s)^\perp = \bigcap_{s \in \mathcal{S}} H_s,$$

we have that $V' = \sum_{s \in \mathcal{S}} k\hat{x}_s$ is stabilized by W , so we deduce the important fact that $\hat{P}_t(\hat{x}_s), \hat{I}_t(\hat{x}_s) \in V'$.

2.3 Some morphisms

We define four morphisms in $\hat{\mathbf{B}}$:

$$\begin{aligned} \hat{j}_r : \hat{\theta}_r \hat{\theta}_r &\rightarrow \hat{\theta}_r \\ \hat{R} \otimes_{\hat{R}^r} \hat{R} \otimes_{\hat{R}^r} \hat{R} \ni p_1 \otimes p_2 \otimes p_3 &\mapsto p_1 \hat{\partial}_r(p_2) \otimes p_3; \\ \hat{m}_r : \hat{\theta}_r &\rightarrow \hat{R} \\ \hat{R} \otimes_{\hat{R}^r} \hat{R} \ni p_1 \otimes p_2 &\mapsto p_1 p_2; \\ \hat{\alpha}_r : \hat{R} &\rightarrow \hat{\theta}_r \hat{\theta}_r \\ 1 &\mapsto \hat{x}_r \otimes 1 \otimes 1 + 1 \otimes 1 \otimes \hat{x}_r. \end{aligned}$$

And finally for $m(s, r) = 2$ we have

$$\begin{aligned} \hat{f}_{s,r} : \hat{\theta}_s \hat{\theta}_r &\rightarrow \hat{\theta}_r \hat{\theta}_s \\ \hat{R} \otimes_{\hat{R}^s} \hat{R} \otimes_{\hat{R}^r} \hat{R} \ni p_1 \otimes p_2 \otimes p_3 &\mapsto p_1 \hat{\partial}_s(p_2) \otimes 1 \otimes \hat{x}_s p_3 + p_1 \hat{P}_s(p_2) \otimes 1 \otimes p_3. \end{aligned}$$

We define the following morphisms from compositions of the previous ones :

- $\hat{p}_r = (\text{id} \otimes \hat{j}_r) \circ (\hat{\alpha}_r \otimes \text{id}) : \hat{\theta}_r \rightarrow \hat{\theta}_r \hat{\theta}_r$;
- $\hat{\epsilon}_r = (\text{id} \otimes \hat{m}_r) \circ \hat{\alpha}_r : \hat{R} \rightarrow \hat{\theta}_r$;
- $\hat{x}_r = (m_r \circ \epsilon_r)/2 : \hat{R} \rightarrow \hat{R}$

By calculating with the explicit formulas we see that the morphism $\hat{x}_r \in \text{End}(\hat{R})$ corresponds to the multiplication by $\hat{x}_r \in \hat{R}$.

2.4 Graphical notation

For sake of the clarity of the exposition, we will introduce a graphical notation for the morphisms. If we write $s_1 s_2 \cdots s_n$ in a diagram, it means $\hat{\theta}_{s_1} \hat{\theta}_{s_2} \cdots \hat{\theta}_{s_n}$. We identify $\hat{R}$ with the blank space. Here we explain what symbol means what morphism:

$$\hat{f}_{r,t} = \begin{array}{|c|c|} \hline r & t \\ \hline t & r \\ \hline \end{array}$$

$$\hat{x}_s = \diamond$$

$$\hat{e}_r = \begin{array}{|c|} \hline r \\ \hline \end{array}$$

$$\hat{m}_r = \begin{array}{|c|} \hline x \\ \hline \end{array}$$

$$\hat{p}_r = \begin{array}{|c|} \hline r \\ \hline \underbrace{\quad \quad}_r \\ \hline \end{array}$$

$$\hat{j}_r = \begin{array}{|c|} \hline \underbrace{\quad \quad}_r \\ \hline r \\ \hline \end{array}$$

$$\hat{\alpha}_r = \begin{array}{|c|} \hline \underbrace{\quad \quad}_r \\ \hline \end{array}$$

$$\hat{m}_r \circ \hat{j}_r = \begin{array}{|c|} \hline \underbrace{\quad \quad}_r \\ \hline \end{array}$$

Pictures are to be understood up to multiplication by non-zero scalars. If we write downwards a sequence of sequences of elements of $\mathcal{S}$, it means a chain of morphisms between the corresponding bimodules. For example if we write

$$\begin{array}{c} r \ s \ t \\ t \ r \ s \\ r \ s \end{array}$$

it means a chain of morphisms

$$\hat{\theta}_r \hat{\theta}_s \hat{\theta}_t \rightarrow \hat{\theta}_t \hat{\theta}_r \hat{\theta}_s \rightarrow \hat{\theta}_r \hat{\theta}_s.$$

As an example, $\begin{array}{|c|} \hline r \\ \hline \underbrace{\quad \quad}_r \\ \hline \end{array}$ means $\hat{j}_r \circ \hat{p}_r$. We lose some information when we look

at the picture of $\hat{x}_s$, because we do not know by which $\hat{x}_s$ are we multiplying, but this will not be a problem for our purposes. So when we have a morphism we can draw its corresponding picture, but in general when we have a picture we cannot completely recover the morphism.

We will use bold letters when we mean a linear combination of this type

of morphisms. For example $\begin{array}{|c|} \hline \mathbf{r} \\ \hline \diamond \mathbf{r} \\ \hline \mathbf{r} \ \mathbf{r} \\ \hline \end{array}$ means $\sum_i \lambda_i \hat{p}_r \circ (\hat{x}_{s_i} \otimes \text{id}_{\hat{\theta}_r})$, with $\lambda_i \in \hat{R}$

and $s_i \in \mathcal{S}$.

2.5 The tensor category T_r

For an introduction to tensor categories and of strict tensor categories with a presentation by generators and relations, we refer the reader to [Ka, chapters XI and XII].

Definition We define the strict tensor category T_r by generators and relations. Its objects are generated by θ_r and by the unit R as tensor category. Its morphisms are generated by :

- $j_r : \theta_r \rightarrow \theta_r \theta_r$
- $m_r : \theta_r \rightarrow R$
- $\alpha_r : R \rightarrow \theta_r \theta_r$

We define p_r, ϵ_r and x_r by the same formulas as in section 2.3 without the hats. The relations defining T_r are the following :

$$1. \epsilon_r = (m_r \otimes \text{id}) \circ \alpha_r$$

$$\overbrace{r \ x}^r = \overbrace{x \ r}^r$$

$$2. p_r = (j_r \otimes \text{id}) \circ (\text{id} \otimes \alpha_r)$$

$$\overbrace{\overbrace{r \ r}^r \ r}^r = \overbrace{r \ \overbrace{r \ r}^r}^r$$

$$3. (\text{id} \otimes (m_r \circ j_r)) \circ (\alpha_r \otimes \text{id}) = \text{id}$$

$$\overbrace{\overbrace{r \ r}^r \ r}^r = \overbrace{r \ r}^r$$

$$4. ((m_r \circ j_r) \otimes \text{id}) \circ (\text{id} \otimes \alpha_r) = \text{id}$$

$$\overbrace{\overbrace{r \ r}^r \ r}^r = \overbrace{r \ r}^r$$

$$5. \quad j_r \circ (\text{id} \otimes j_r) = j_r \circ (j_r \otimes \text{id}) \quad \begin{array}{c} r \quad r \quad r \\ \underbrace{\quad} \\ r \quad r \\ \underbrace{\quad} \\ r \end{array} = \begin{array}{c} r \quad r \quad r \\ \underbrace{\quad} \\ r \quad r \\ \underbrace{\quad} \\ r \end{array}$$

$$6. \quad j_r \circ \alpha_r = 0 \quad \underbrace{\overline{rr}} = 0$$

$$7. \quad \text{id} \otimes m_r = m_r \otimes \text{id} + j_r x_r - x_r j_r \quad \begin{array}{c} r \quad x \\ r \end{array} = \begin{array}{c} x \quad r \\ r \end{array} + \begin{array}{c} r \quad r \\ \underbrace{\quad} \\ r \\ r^\diamond \end{array} + \begin{array}{c} r \quad r \\ \underbrace{\quad} \\ r \\ \diamond r \end{array}$$

$$8. \quad j_r \circ (\text{id} \otimes x_r \otimes \text{id}) = \begin{array}{c} r \quad r \\ r^\diamond r \\ \underbrace{\quad} \\ r \end{array} = \begin{array}{c} x \quad r \\ r \end{array} + \begin{array}{c} r \quad r \\ \underbrace{\quad} \\ r \\ \diamond r \end{array}$$

$$= (m_r \otimes \text{id}) - (x_r \otimes \text{id}) \circ j_r$$

The following definition is needed to state the proposition 2.1.

Definition Let A be a commutative ring and $\mathcal{C}$ an A -linear category. If R is a commutative A -algebra, we define the category $\mathcal{C} \otimes_A R$ in the following way : it has the same objects as $\mathcal{C}$ and its morphisms are defined by the formula

$$\text{Hom}_{\mathcal{C} \otimes_A R}(M, N) = \text{Hom}_{\mathcal{C}}(M, N) \otimes_A R$$

Let $\mathcal{A}$ be the subring of $\text{End}_{T_r}(R)$ generated the set $\{x_s\}_{s \in S}$.

Proposition 2.1 *Let W be a Weyl group of type A_1 and let $\mathcal{A}$ be defined as above. The application $x_s \mapsto \hat{x}_s$ extends to a morphism $\mathcal{A} \rightarrow \hat{R}$ and there exists an equivalence of $\hat{R}$ -linear tensor categories between $\hat{\mathbf{B}}(W)$ and $T_r \otimes_{\mathcal{A}} \hat{R}$.*

This proposition is a special case of theorem 3.1 that will be proved in the sequel.

2.6 Some notation for the morphisms

Let $(s_1, \dots, s_n) \in \mathcal{S}^n$. In the article [Li1], some basis are constructed (called BFL basis) as a right $\hat{R}$ -module of $\text{Hom}_{(\hat{R}, \hat{R})}(\hat{\theta}_{s_1} \cdots \hat{\theta}_{s_n}, \hat{R})$. We will fix one such basis by taking (with the notations of the paper [Li1]) $p(n, x, \bar{t})$ a m -tuple with m minimal. To recall what is this basis, we start with a definition.

Definition If they have a meaning, we define in $\text{Hom}(\hat{\theta}_{u_1} \cdots \hat{\theta}_{u_l}, \hat{\theta}_{t_1} \cdots \hat{\theta}_{t_k})$ the following morphisms,

1. ${}^i\hat{j} := \text{id}^i \otimes \hat{j}_{u_{i+1}} \otimes \text{id}^{l-i-2}$
2. ${}^i\hat{m} := \text{id}^i \otimes \hat{m}_{u_{i+1}} \otimes \text{id}^{l-i-1}$
3. ${}^i\hat{\alpha}_s := \text{id}^i \otimes \hat{\alpha}_r \otimes \text{id}^{l-i}$
4. ${}^i\hat{f} := \text{id}^i \otimes \hat{f}_{u_{i+1}, u_{i+2}} \otimes \text{id}^{l-i-2}$
5. ${}^i\hat{p} := \text{id}^i \otimes \hat{p}_r \otimes \text{id}^{l-i-1}$
6. ${}^i\hat{\epsilon}_s := \text{id}^i \otimes \hat{\epsilon}_r \otimes \text{id}^{l-i-1}$
7. ${}^i\hat{x}_s := \text{id}^i \otimes \hat{x}_r \otimes \text{id}^{l-i-1}$

Let $\text{Mo} = \{j, m, \alpha_s, f, p, \epsilon_s, x_s\}$. For $d \in \text{Mo}$ we define $\hat{d}^i$ in almost the same way, the only difference is that we put id^i in the right. For example $\hat{j}^i = \text{id}^{l-i-2} \otimes \hat{j}_{u_{i+1}} \otimes \text{id}^i$.

Now we are able to define $\hat{m}(t), \hat{\text{ch}}(t)$ (chain) and $\widehat{\text{cch}}(t)$ (complete chain) :

- $\hat{m}(t) = \hat{m}^t$ $\mathcal{X}$
- $\hat{\text{ch}}(t) = \hat{j}^t \circ \hat{f}^{t+1} \circ \hat{f}^{t+2} \circ \dots \circ \hat{f}^{t'}$
 $\begin{array}{c} \text{---} \\ \text{---} \\ \dots \\ \text{---} \\ \text{---} \end{array}$

- $\widehat{\text{cch}}(t) = \widehat{m}^t \circ \widehat{\text{ch}}(t)$

Definition Let $\text{No} = \{\widehat{m}, \widehat{\text{ch}}, \widehat{\text{cch}}\}$. We say that $(\widehat{g}_q(t_q), \dots, \widehat{g}_1(t_1))$, with $\widehat{g}_i \in \text{No}$, is a good g -expression of the morphism $\widehat{g}_q(t_q) \circ \dots \circ \widehat{g}_1(t_1)$. If $t_{p+1} < t_p$ for all $1 \leq p \leq q$ then we say that the good g -expression is in the good order.

Definition Let $\nu = (\widehat{g}_q(t_q), \dots, \widehat{g}_1(t_1))$ be a good g -expression. If $m \leq q$ and $\widehat{g}_m(t_m) \circ \dots \circ \widehat{g}_1(t_1) : \widehat{\theta}_{s_1} \dots \widehat{\theta}_{s_n} \rightarrow \widehat{\theta}_{u_1} \dots \widehat{\theta}_{u_l}$ we say that $\text{Ima}(\nu, m) = (u_1, \dots, u_l)$.

Definition Let $\bar{t} = (t_1, \dots, t_p) \in \mathcal{S}^p$. We say that the i^{th} element of $\bar{t}$ is of left type if there exists $j < i$, with $t_j = t_i$ and $m(t_r, t_i) = 2$ for all $j < r < i$.

2.7 A basis of the morphism spaces in the right-angled case

We start with a definition.

Definition We say that a good g -expression in good order $(\widehat{g}_q(t_q), \dots, \widehat{g}_1(t_1))$ satisfies property (P) if for all $1 \leq m \leq q$ such that the t_m^{th} element of $\text{Ima}(\nu, m)$ is of left type, we have $\widehat{g}_{m+1}(t_{m+1}) = \widehat{\text{ch}}(t_m - 1)$ or $\widehat{\text{cch}}(t_m - 1)$.

The following is a corollary of theorem [Li1, thm. 5.1] :

Proposition 2.2 Let $(W, \mathcal{S})$ be a right-angled Coxeter system. Let $(s_1, \dots, s_n) \in \mathcal{S}^n$. The set

$$\widehat{FL}(s_1, \dots, s_n) = \{ \text{good } g\text{-expressions in good order of morphisms in } \text{Hom}(\widehat{\theta}_{s_1} \dots \widehat{\theta}_{s_n}, \widehat{R}) \text{ satisfying property (P)} \}.$$

is an $\widehat{R}$ -basis of $\text{Hom}_{(\widehat{R}, \widehat{R})}(\widehat{\theta}_{s_1} \dots \widehat{\theta}_{s_n}, \widehat{R})$ called "Light leaves basis".

For every $M, N \in \widehat{\mathbf{B}}(W)$, we define the two morphisms :

- $\widehat{F}_s(M, N) : \text{Hom}(\widehat{\theta}_s M, N) \rightarrow \text{Hom}(M, \widehat{\theta}_s N)$ that sends f to $(\text{id}_{\widehat{\theta}_s} \otimes f) \circ (\widehat{\alpha}_s \otimes \text{id}_M)$
- $\widehat{G}_s(M, N) : \text{Hom}(M, \widehat{\theta}_s N) \rightarrow \text{Hom}(\widehat{\theta}_s M, N)$ that sends g to $((\widehat{m}_s \circ \widehat{j}_s) \otimes \text{id}_N) \circ (\text{id}_{\widehat{\theta}_s} \otimes g)$

They are inverse to each other (see [Li1, lemma 3.3] and its proof), so we can define a basis of $\text{Hom}(\widehat{\theta}_{s_1} \cdots \widehat{\theta}_{s_n}, \widehat{\theta}_{t_1} \cdots \widehat{\theta}_{t_k})$:

$$\widehat{FL}(s_1, \dots, s_n; t_1, \dots, t_k) := \widehat{F}_{t_1} \circ \cdots \circ \widehat{F}_{t_{k-1}} \circ \widehat{F}_{t_k} \circ \widehat{FL}(s_1, \dots, s_n).$$

3 The tensor category $\mathbf{T}$

3.1

Definition Let $(W, \mathcal{S})$ be a right-angled Coxeter system and V a reflection faithful representation of W . We will define the tensor category $\mathbf{T}(W, V)$ by generators and relations. Its objects are generated as tensor category by θ_r for all $r \in \mathcal{S}$, and by the unit R . Its morphisms are generated by

- $j_r : \theta_r \rightarrow \theta_r \theta_r$
- $m_r : \theta_r \rightarrow R$
- $\alpha_r : R \rightarrow \theta_r \theta_r$
- $f_{sr} : \theta_s \theta_r \rightarrow \theta_r \theta_s$

We define p_r, ϵ_r and x_r by the the same formulas as in section 2.3 without the hat. For $s, r \in \mathcal{S}$, let us write (see section 2.2)

$$\widehat{P}_t(\widehat{x}_s) = \sum_{r \in \mathcal{S}} \lambda_{t,s}^r \widehat{x}_r \quad , \quad \widehat{I}_t(\widehat{x}_s) = \mu_{t,s} \widehat{x}_t \quad \text{and} \quad \widehat{\partial}_t(\widehat{x}_s) = \frac{\widehat{I}_t(\widehat{x}_s)}{\widehat{x}_t}$$

We define in the same way

$$P_t(x_s) = \sum_{r \in \mathcal{S}} \lambda_{t,s}^r x_r \quad , \quad I_t(x_s) = \mu_{t,s} x_t \quad \text{and} \quad \partial_t(x_s) = \frac{I_t(x_s)}{x_t},$$

where $\lambda_{t,s}^r$ and $\mu_{t,s}$ are elements of the field k .

We define a monomial as a product of x'_s 's, and a polynomial $\lambda \in \text{End}(R)$ as a linear combination of monomials with coefficients in k . We will note $\mathcal{A} \subseteq \text{End}(R)$ the subring of polynomials.

The relations defining T are the first 7 relations of definition 2.5 and the following new relations (from **a** to **e** we assume that $m(s, r) = m(r, t) = m(s, t) = 2$) :

a) $f_{sr} \circ f_{r,s} = \text{id}$

$$\begin{array}{c} \overline{sr} \\ \overline{rs} \\ sr \end{array} = \begin{array}{c} sr \end{array}$$

b) $(m_r \otimes \text{id}) \circ f_{sr} = \text{id} \otimes m_r$

$$\begin{array}{c} \overline{sr} \\ \overline{rs} \\ s \end{array} = \begin{array}{c} sr \\ s \end{array}$$

c) $(j_s \otimes \text{id}) \circ (\text{id} \otimes f_{r,s}) = f_{r,s} \circ (\text{id} \otimes j_s) \circ (f_{sr} \otimes \text{id})$

$$\begin{array}{c} s \overline{rs} s \\ s s r \\ s \quad r \end{array} = \begin{array}{c} \overline{sr} s \\ r s s \\ \underbrace{\quad} \\ r s \\ s \quad r \end{array}$$

d) $(\text{id} \otimes f_{sr}) \circ (\alpha_s \otimes \text{id}) =$
 $= (f_{r,s} \otimes \text{id}) \circ (\text{id} \otimes \alpha_s)$

$$\begin{array}{c} r \\ \overline{sr} r \\ s r s \end{array} = \begin{array}{c} r \\ r \overline{sr} \\ s r s \end{array}$$

e) $(\text{id} \otimes f_{sr}) \circ (f_{s,t} \otimes \text{id}) \circ (\text{id} \otimes f_{r,t}) =$
 $(f_{r,t} \otimes \text{id}) \circ (\text{id} \otimes f_{s,t}) \circ (f_{sr} \otimes \text{id})$

$$\begin{array}{c} s r t \\ s t r \\ t s r \\ t r s \end{array} = \begin{array}{c} s r t \\ r s t \\ r t s \\ t r s \end{array}$$

f) $f_{t,r} \circ (\text{id}_{\theta_r} \otimes x_r \otimes \text{id}_{\theta_r}) =$
 $(P_t(x_s) \otimes \text{id}_{\theta_r \theta_t}) \circ f_{t,r} + (\text{id}_{\theta_r \theta_t} \otimes I_t(x_s)) \circ f_{t,r}$

$$\begin{array}{c} t r \\ \overline{tr} \\ r t \end{array} = \begin{array}{c} \overline{tr} \\ \mathbf{r} \mathbf{t} \\ \diamond \mathbf{r} \mathbf{t} \end{array} + \begin{array}{c} \overline{tr} \\ \mathbf{r} \mathbf{t} \\ \mathbf{r} \mathbf{t}^\diamond \end{array}$$

$$\begin{aligned} \mathbf{g}) \quad j_r \circ (\text{id}_{\theta_r} \otimes x_r \otimes \text{id}_{\theta_r}) &= \partial_r(x_s)m_r \otimes \text{id} + \\ &+ (P_r(x_s) \otimes \text{id} - x_s \partial_r(x_s) \otimes \text{id}) \circ j_r \end{aligned} \quad \underbrace{\begin{array}{c} r \quad r \\ r \diamond r \\ r \end{array}} = \underbrace{\begin{array}{c} x \quad r \\ r \end{array}} + \underbrace{\begin{array}{c} \mathbf{r} \quad \mathbf{r} \\ \mathbf{r} \\ \diamond \mathbf{r} \end{array}}$$

Remark We can say heuristically that **a**, **b**, **c** and **d** say that the f_{sr} "commute" with everything, **e** is the hexagon relation typical in the symmetric monoidal categories. The last two relations tells us how to "take down" the x'_s s.

The ring $\text{End}(R)$ is commutative because of general results in tensor categories (see [Ka, prop. X1.2.4]). As before, for $s \in \mathcal{S}$, we make $x_s \in \text{Arr}(\mathbf{T}(W, V))$ to act in $\hat{R}$ in the same way as $\hat{x}_s \in \hat{R}$ does. We deduce an action of $\mathcal{A}$ in $\hat{R}$.

The following is the central result of this paper :

Theorem 3.1 *Let $(W, \mathcal{S})$ be a right-angled Coxeter group. The functor that sends θ_s to $\hat{\theta}_s$, $j_s \otimes 1$ to $\hat{j}_s$, etc. is an equivalence of $\hat{R}$ -linear tensor categories between $\mathbf{T}(W, V) \otimes_{\mathcal{A}} \hat{R}$ and $\hat{\mathbf{B}}(W, V)$.*

Proof. We repeat all definitions in sections 2.6 and 2.7 taking out the hat, so we define ${}^i d$ and d^i , for $d \in \text{Mo}$, $m(t)$, $\text{ch}(t)$, $\text{cch}(t)$, we define a good g -expression and to be of left type, FL , $F_s(M, N)$ and $G_s(M, N)$

We will put $\mathbf{T} = \mathbf{T}(W, V) \otimes_{\mathcal{A}} R$ and $\hat{\mathbf{B}} = \hat{\mathbf{B}}(W, V)$. We define a functor $\mathfrak{F}\mathbf{u}$ from $\mathbf{T}$ to $\hat{\mathbf{B}}$. We define $\mathfrak{F}\mathbf{u}(R) = \hat{R}$, and for all $s \in \mathcal{S}$, $\mathfrak{F}\mathbf{u}(\theta_s) = \hat{\theta}_s$. If M and M' are objects of $\mathbf{T}$, we define $\mathfrak{F}\mathbf{u}(M \otimes M') = \mathfrak{F}\mathbf{u}(M) \otimes \mathfrak{F}\mathbf{u}(M')$.

For all $s \in \mathcal{S}$ we define $\mathfrak{F}\mathbf{u}(j_s \otimes \lambda) = \hat{j}_s \lambda$, $\mathfrak{F}\mathbf{u}(m_s \otimes \lambda) = \hat{m}_s \lambda$, etc. As we know explicitly all the morphisms in $\hat{\mathbf{B}}$, we can easily verify that all the relations are satisfied in $\hat{\mathbf{B}}$, so by [Ka, proposition XII.1.4] we have that $\mathfrak{F}\mathbf{u}$ defines a tensor functor. By [Li1, thm. 5.1] we know that the set of morphisms $\{\hat{j}_r, \hat{m}_r, \hat{\alpha}_r, \hat{f}_{s,r}\}$ generates (as tensor category) all the morphisms in $\hat{\mathbf{B}}$. So we only need to prove that for all $M, N \in \mathbf{T}$, the map $\mathfrak{F}\mathbf{u} : \text{Hom}_{\mathbf{T}}(M, N) \rightarrow \text{Hom}_{\hat{\mathbf{B}}}(\mathfrak{F}\mathbf{u}(M), \mathfrak{F}\mathbf{u}(N))$ is injective.

We start by proving the following

Lemma 3.2 *The applications $F_s(M, N)$ and $G_s(M, N)$ are inverse to each other*

Proof.

$$\begin{aligned}
F_s(M, N) \circ G_s(M, N)(g) &= F_s(M, N)((m_s \circ j_s) \otimes \text{id}_N \circ (\text{id}_{\theta_s} \otimes g)) \\
&= \{\text{id}_{\theta_s} \otimes [((m_s \circ j_s) \otimes \text{id}_N) \circ (\text{id}_{\theta_s} \otimes g)]\} \circ (\alpha_s \otimes \text{id}_M) \\
&= [(\text{id}_{\theta_s} \otimes (m_s \circ j_s) \otimes \text{id}_N) \circ (\text{id}_{\theta_s}^2 \otimes g)] \circ (\alpha_s \otimes \text{id}_M) \\
&= (\text{id}_{\theta_s} \otimes (m_s \circ j_s) \otimes \text{id}_N) \circ (\alpha_s \otimes g) \\
&= (\text{id}_{\theta_s} \otimes (m_s \circ j_s) \otimes \text{id}_N) \circ (\alpha_s \otimes \text{id}_{\theta_s} \otimes \text{id}_N) \circ g \\
&= (\{[\text{id}_{\theta_s} \otimes (m_s \circ j_s)] \circ (\alpha_s \otimes \text{id}_{\theta_s})\} \otimes \text{id}_N) \circ g \\
&= (\text{id}_{\theta_s} \otimes \text{id}_N) \circ g \\
&= g
\end{aligned}$$

If (0) is the relation $(f_1 \otimes g_1) \circ (f_2 \otimes g_2) = (f_1 \circ f_2) \otimes (g_1 \circ g_2)$ (relation satisfied in all tensor categories), then all but the next to last equality are derived from (0). The next to last equality is derived from relation 3 (see definition 2.5). In a similar way we prove that $G_s(M, N) \circ F_s(M, N)(f) = f$ using relation 4. $\square$

Definition Consider two morphisms $g : M_1 \rightarrow N_1$ and $f : M_2 \rightarrow N_2$. The relation $(f \otimes \text{id}_{N_1}) \circ (\text{id}_{M_2} \otimes g) = (\text{id}_{N_2} \otimes g) \circ (f \otimes \text{id}_{M_1})$, satisfied in all tensor categories, will be called commutation relation.

3.2

Lemma 3.3 *Let us suppose that for every sequence $(s_1, \dots, s_n)$, $f \in \text{Hom}(\theta_{s_1} \dots \theta_{s_n}, R)$ implies that $f = \sum_i a_i \lambda_i$, where $a_i \in FL(s_1, \dots, s_n)$ and the λ_i are polynomials. Then for every couple of sequences $(s_1, \dots, s_n)$ and $(t_1, \dots, t_k)$, $f' \in \text{Hom}(\theta_{s_1} \dots \theta_{s_n}, \theta_{t_1} \dots \theta_{t_k})$ implies that $f' = \sum_i a'_i \lambda'_i$, where $a'_i \in FL(s_1, \dots, s_n; t_1 \dots t_k)$ and the λ'_i are polynomials.*

Proof. By hypothesis, $G_{t_k} \circ \dots \circ G_{t_1}(f') = \sum_i a_i \lambda_i$, where $a_i \in FL(t_k, \dots, t_1, s_1, \dots, s_n)$ and the λ_i are polynomials. Then

$$\begin{aligned}
f' &= F_{t_1} \circ \dots \circ F_{t_k} \circ G_{t_k} \circ \dots \circ G_{t_1}(f') \\
&= \sum_i F_{t_1} \circ \dots \circ F_{t_k}(a_i \lambda_i) \\
&= \{\sum_i F_{t_1} \circ \dots \circ F_{t_k}(a_i)\} \lambda_i
\end{aligned}$$

and by definition $\sum_i F_{t_1} \circ \dots \circ F_{t_k}(a_i) \in FL(s_1, \dots, s_n; t_1 \dots t_k)$. $\square$

3.3

From this lemma we can conclude that to complete the proof of theorem 3.1, it suffices to prove that for every sequence $(s_1, \dots, s_n)$, $f \in \text{Hom}(\theta_{s_1} \dots \theta_{s_n}, R)$

implies that $f = \sum_i a_i \lambda_i$, where $a_i \in FL(s_1, \dots, s_n)$ and the λ_i are polynomials.

Definition For a sequence $s_1, \dots, s_n \in \mathcal{S}$, we will say that $\theta_{s_1} \cdots \theta_{s_n}$ is a basic bimodule.

Every morphism between basic bimodules can be written as a sum of terms of the following type: ${}^{i\omega}d_\omega \circ \cdots \circ {}^{i1}d_1$, with $d_i \in \text{Lo} = \{j_s, m_s, f_{sr}, \alpha_s \mid s, r \in \mathcal{S}\}$.

Definition In the sequel an *expression* of a morphism g between basic bimodules means a sequence $({}^{i\omega}d_\omega, \dots, {}^{i1}d_1)$, with $d_i \in \text{Lo}$, such that ${}^{i\omega}d_\omega \circ \cdots \circ {}^{i1}d_1 = g$. If ν is an expression of g , we define $\overline{\nu} = g$, and we say that ν is representing g . An *R-expression* is an expression representing a morphism from a basic bimodule to R . Sometimes we will consider a good g -expression simply like an expression in the obvious way. Finally, if we consider a formal $\mathcal{A}$ -linear combination of expressions $\nu = \sum_{i \in I} \lambda_i \nu_i$, with $\lambda_i \in \mathcal{A}$, we define $\overline{\nu} = \sum_{i \in I} \lambda_i \overline{\nu}_i$

Definition If $({}^{i\omega}d_\omega, \dots, {}^{i1}d_1)$ is an expression of g , we say that the k^{th} term of this expression is the morphism ${}^{ik}d_k$. We say that ${}^{i\omega}d_\omega$ is the last term of this expression, ${}^{i1}d_1$ is the first term, and ω is the length of the expression.

When i is not important, we will write d instead of ${}^i d$, and when the s is not important we will write for example x for x_s and f for f_{sr} .

Definition We define G as the set of all R -expressions $({}^{i\omega}d_\omega, \dots, {}^{i1}d_1)$ with $d_i \neq \alpha_s$ for all i and for all $s \in \mathcal{S}$.

Definition We will say that $\nu = ({}^{i\omega}h_\omega, \dots, {}^{i1}h_1)$ with $h_i \in \text{Mo}$ for all $1 \leq i \leq \omega$ is a generalized expression of ${}^{i\omega}h_\omega \circ \cdots \circ {}^{i1}h_1$.

Let

$${}^{i\omega}h_\omega \circ \cdots \circ {}^{i1}h_1 = \sum_z {}^{p_{u,z}}h'_{u,z} \circ \cdots \circ {}^{p_{1,z}}h'_{1,z}$$

be one of the relations 1-8 or a-g defining the tensorial category $\mathbf{T}$, where all h_i and $h'_{i,z}$ are elements of Mo . For all natural numbers $b \geq 0$ we say that $X = ({}^{i\omega+b}h_\omega, \dots, {}^{i1+b}h_1)$ is a left generalized expression and $\sum_z ({}^{p_{u,z}+b}h'_{u,z}, \dots, {}^{p_{1,z}+b}h'_{1,z})$ is a right generalized expression correspondig to X .

Definition Let us consider ν a generalized expression. We will say that we *apply* to ν one of the relations 1-8 or a-g, defining the tensorial category $\mathbf{T}$, and we obtain a finite sum $\sum_i \nu'_i$ of generalized expressions if $\sum_i \nu'_i$ is the result of changing in ν a substring X that is a left generalized expression by a right generalized expression corresponding to X .

4 A brief summary of what we will do

If we have an expression $\nu \in G$, we will start by defining $\nu\{\#m - \text{bad}\}$ and $\nu\{\#j - \text{bad}\} \in \mathbb{N}$, that are measures of how far is ν from being in the light leaves basis. We will see that an expression ν is in $FL(s_1, \dots, s_n)$ if and only if ν is a good g -expression in the good order, and $\nu\{\#m - \text{bad}\} = \nu\{\#j - \text{bad}\} = 0$.

In each section we start with an expression satisfying some properties. Then we apply some relations to this expression and we arrive to another expression (eventually an $\mathcal{A}$ -linear combination of expressions) which represents the same morphism, but satisfying new properties. In the following list, we show what properties satisfies the expression with which we start in each section, and what properties satisfies the expression to which we arrive :

- *Section 4* : $\nu \in G \rightsquigarrow \nu \in G$, $\nu\{\#m - \text{bad}\} = 0$
- *Section 5* : $\nu \in G \rightsquigarrow \nu \in G$, ν a good g -expression
- *Section 6* : $\nu \rightsquigarrow \nu \in G$
- *Section 7* : ν a good g -expression $\rightsquigarrow \nu$ a good g -expression in the good order
- *Section 8.1* : $\nu \in G \rightsquigarrow \nu$ a good g -expression in the good order with $\nu\{\#m - \text{bad}\} = 0$
- *Section 8.2* : ν a good g -expression in the good order with $\nu\{\#m - \text{bad}\} = 0 \rightsquigarrow \nu$ a good g -expression in the good order with $\nu\{\#m - \text{bad}\} = \nu\{\#j - \text{bad}\} = 0$

5 Some numbers associated to an expression

Definition Let $\nu = ({}^{i_k}d_k, \dots, {}^{i_1}d_1)$ be an expression for g , and let the sequence of integers $(i'_1, i'_2, \dots, i'_k)$ be such that $\bar{\nu} = d_k^{i'_k} \circ \dots \circ d_1^{i'_1}$. We define $\nu_r = ({}^{i_r}d_r, \dots, {}^{i_1}d_1)$ the truncation of ν at r .

If $\bar{\nu}_r : \theta_{s_1} \dots \theta_{s_n} \rightarrow \theta_{t_1} \dots \theta_{t_p}$, we define $\hat{\nu}_r = (t_1, \dots, t_p) \in \mathcal{S}^p$. For $b \in \{j, m, \alpha, f\}$ we define $\nu[b] = \{p; 1 \leq p \leq k, d_p = b\}$.

We say that r is m -bad (resp. j -bad) for ν if $d_r = m$ (resp. $d_r = j$) and the $(i_r + 1)^{th}$ element of $\hat{\nu}_r$ is of left type.

We define the following sets associated to ν :

- $A_m(\nu) = \{r ; r \text{ is } m\text{-bad for } \nu\}$
- $A_j(\nu) = \{r ; r \text{ is } j\text{-bad for } \nu\}$

We define the following elements associated with ν :

- $\nu\{\#m\text{-bad}\} = \text{card}(A_m(\nu)) \in \mathbb{N}$
- $\nu\{\#j\text{-bad}\} = \text{card}(A_j(\nu)) \in \mathbb{N}$

Let $\nu[j] = \{a_1, \dots, a_p\}$ with $a_1 < a_2 < \dots < a_p$.

- $\nu\{\text{positions of } j\text{'s}\} = (a_1 + i'_{a_1}, \dots, a_k + i'_{a_k}) \in \mathbb{N}^k$
- $\nu\{\#f\} = \text{card}(\nu[f]) \in \mathbb{N}$
- $\nu\{f \text{ to the right}\} = \sum_{p \in \nu[f]} (i_p) \in \mathbb{N}$
- $\nu\{\text{depth } m \text{ and } j\} = \sum_{p \in \nu[m] \cup \nu[j]} (p) \in \mathbb{N}$
- $\nu\{m \text{ far from bottom}\} = \sum_{p \in \nu[m]} (k - p) \in \mathbb{N}$
- $\nu\{\min m\text{-bad}\} = \begin{cases} \min A_m(\nu) & \text{if } A_m(\nu) \neq \emptyset \\ 0 & \text{if } A_m(\nu) = \emptyset \end{cases}$

- $\nu\{\#m, j \text{ after min. } m - \text{bad}\} = \text{card}(\{p > \nu\{\text{min } m - \text{bad}\} \mid i_p = 1 \text{ or } i_p = 2\}) \in \mathbb{N}$
- $\nu\{\text{function of } m\text{-bads}\} = (\nu\{\#m, j \text{ after min. } m\text{-bad}\}, i_{\nu\{\text{min } m\text{-bad}\}}) \in \mathbb{N}^2$
- $\nu\{\text{max. } j - \text{bad}\} = \begin{cases} \max A_j(\nu) & \text{if } A_j(\nu) \neq \emptyset \\ 0 & \text{if } A_j(\nu) = \emptyset \end{cases}$

If $p \in \nu[1]$ (resp. $p \in \nu[2]$) $\hat{\nu}_p = (t_1, \dots, t_k)$ then we define $\pi_1(p)$ (resp. $\pi_2(p)$) $= \text{card}\{m \leq i_p \mid t_m = t_{i_{p+1}}\}$. Finally we define

$$\nu\{m, j \text{ equal to left}\} = \sum_{p \in \nu[1] \cup \nu[2]} (\pi_1(p) + \pi_2(p)) \in \mathbb{N}$$

6 Restriction to the case $\nu\{\#m\text{-bad}\} = 0$

Proposition 6.1 *For every $\nu \in G$ there exists a set Δ , polynomials λ_δ and elements $\nu_\delta \in G$ such that $\overline{\nu} = \sum_{\delta \in \Delta} \lambda_\delta \nu_\delta$ and such that $\nu_\delta\{\#m - \text{bad}\} = 0$ for all $\delta \in \Delta$.*

Proof.

We will start by constructing $\mathcal{F}_1(\nu), \mathcal{F}_2(\nu)$, linear combinations of expressions such that $\overline{\mathcal{F}_i(\nu)} = \overline{\nu}$ for $1 \leq i \leq 2$.

6.0.1 $\mathcal{F}_1(\nu)$: “Taking out the x_r ’s”

Definition If $\nu = ({}^{i_p}d_p, \dots, {}^{i_{r+1}}d_{r+1}, {}^i x_s, {}^{i_r}d_r, \dots, {}^{i_1}d_1)$ is a generalized expression, with $d_l \in \text{Lo} - \{\alpha_s\}_{s \in \mathcal{S}}$ for all $1 \leq l \leq p$, we say that $\nu \in G_r^p$.

Let $\nu \in G_r^p$. We take x_s as far to the left as possible (or down in the picture) with commutation relations. If it does not arrive to the last term,

we obtain a string of the form $\underbrace{{}^s s}_{s} \text{ or } \underbrace{{}^t r}_{r \ t}$. If we are in the first case we

apply relation **g** and if we are in the second case, we apply relation **f** and we obtain

$$\mathcal{F}_1^1(\nu) = \sum_{i \in I_1} w_i^1 + \sum_{b \in B_1} g_b^1,$$

with $\bar{\nu} = \overline{\mathcal{F}_1^1(\nu)}$, and where I_1 and B_1 are finite sets, $g_b^1 \in G$ (corresponding to $\begin{smallmatrix} x & r \\ & r \end{smallmatrix}$ in relation **g**) and

$$w_i^1 \in G_{r_i^1}^p, \text{ with } r_i^1 \geq r + 1 \quad (1)$$

We define $\mathcal{F}_1^n$ inductively : let $\mathcal{F}_1^n(\nu) = \sum_{i \in I_n} w_i^n + \sum_{b \in B_n} g_b^n$. We define $\mathcal{F}_1^{n+1}(\nu) = \sum_{i \in I_n} \mathcal{F}_1^1(w_i^n) + \sum_{b \in B_n} g_b^n$. By induction and inequality (1) we deduce that $w_i^N \in G_{r_i^N}^p$, with $r_i^N \geq r + N$. We conclude that for $N \gg 0$, $\mathcal{F}_1^N(\nu) = \mathcal{F}_1^{N+1}(\nu)$. We define $\mathcal{F}_1(\nu) = \mathcal{F}_1^N(\nu)$.

As $\mathcal{F}_1(\nu) = \sum_{i \in I_N} w_i^N + \sum_{b \in B_N} g_b^N$ with $w_i^N \in G_{p+1}^p$, and as $w \in G_{p+1}^p \Rightarrow w = \lambda g$ with λ a polynomial and $g \in G$, we have :

Lemma 6.2 *There exists polynomials λ_i and elements $g_i \in G$ such that $\mathcal{F}_1(\nu) = \sum_{i \in I} \lambda_i g_i$,*

Remark Essentially when we take the x'_r 's out of ν the only thing we change in the picture of ν is eventually changing some j 's by m 's.

6.1 $\mathcal{F}_2(\nu)$

Let $\nu \in G$. If $\nu\{\min m - \text{bad}\} = 0$ we define $\mathcal{F}_2(\nu) = \nu$. Now let us suppose $\nu\{\min m - \text{bad}\} \neq 0$. By definition, in the $\nu\{\min m - \text{bad}\}^{\text{th}}$ position of ν we have a picture like this one : $\cdots r \cdots x$, where r commutes with all the elements between the two r 's. By relation **a**. applied several times we obtain

$$\begin{array}{c} \cdots \overbrace{r} \cdots \quad r \cdots \\ \cdots \overbrace{r} \cdots \quad r \cdots \\ \quad \ddots \\ \quad \quad \overbrace{r} \quad r \\ \cdots r \cdots x = \quad \quad \overbrace{r} \quad x \cdots \\ \quad \quad \quad \ddots \\ \quad \quad \quad \overbrace{r} \cdots \\ \quad \quad \quad \ddots \\ \quad \quad \overbrace{r} \cdots \\ \cdots \overbrace{r} \cdots \end{array}$$

Or in formulas : $y m = {}^x f \circ {}^x f \circ {}^{x+1} f \circ \dots \circ {}^{y-2} f \circ y m \circ {}^{y-2} f \circ \dots \circ {}^{x+1} f \circ {}^x f$. In the right hand side of the picture we apply relation 7. We obtain $\bar{\nu} = \overline{\nu_1 + \nu_2 + \nu_3}$, where $\nu_1 \in G$ and $\nu_2, \nu_3 \in G_r^p$ for some r . We define $\mathcal{F}_2^1(\nu) = \nu_1 + \mathcal{F}_1(\nu_2) + \mathcal{F}_1(\nu_3)$.

If we write $\mathcal{F}_2^1(\nu) = \sum_i \lambda_i^1 g_i^1$, as

$$\begin{aligned} & \text{card}(\{1 \leq p \leq \nu\{\min m - \text{bad}\} \mid i_p = 1 \text{ or } i_p = 2\}) + \\ & + \nu\{\#m, j \text{ after min. } m - \text{bad}\} = \text{card}(\{p \mid i_p = 1 \text{ or } i_p = 2\}) \end{aligned}$$

is a constant for all the expressions of $\bar{\nu}$, by construction we have

$$\mathcal{F}_2^1(g_i)\{\text{function of } m - \text{bads}\} < \nu\{\text{function of } m - \text{bads}\}. \quad (2)$$

If $\mathcal{F}_2^N(\nu) = \sum_i \lambda_i^N g_i^N$, we define $\mathcal{F}_2^{N+1}(\nu) = \sum_i \lambda_i^N \mathcal{F}_2^1(g_i^N)$, and by equation 2 and the fact that $\nu\{\text{function of } m - \text{bads}\} \geq (0, 0)$ we conclude that there exists $N \gg 0$ such that $\mathcal{F}_2^N(\nu) = \mathcal{F}_2^{N+1}(\nu)$. We then define $\mathcal{F}_2^N(\nu) = \mathcal{F}_2(\nu)$. This means in particular that if $\mathcal{F}_2(\nu) = \sum_{\delta \in \Delta} \lambda_\delta \nu_\delta$, then $\nu_\delta\{\#m - \text{bad}\} = 0$, which proves proposition 6.1 $\square$

7

Proposition 7.1 *For every $\nu \in G$ there exists a set Δ , polynomials λ_δ and elements $\nu_\delta \in G$ such that $\bar{\nu} = \overline{\sum_{\delta \in \Delta} \lambda_\delta \nu_\delta}$ and such that*

- $\nu_\delta\{\#m - \text{bad}\} = 0$ for all $\delta \in \Delta$.
- If the k^{th} term of ν_δ is ${}^i f$ then the $(k+1)^{\text{th}}$ term is ${}^{i+1} f$ or ${}^{i+1} j$.

Remark The second condition means that ν_δ is a good g -expression.

7.1

Proof.

We start with some definitions.

Definition • Relation $\begin{array}{c} s \quad \overbrace{s \quad r} \\ \overbrace{s \quad r} \quad s \\ r \quad \underbrace{s \quad s} \\ r \quad s \end{array} = \begin{array}{c} \overbrace{s \quad s} \quad r \\ \underbrace{s \quad r} \\ r \quad s \end{array}$ can be deduced from **a.** and **c.** and will be called **c'**.

- Relation $\frac{r}{s} \frac{s}{x} = \frac{x}{s} \frac{s}{s}$ can be deduced from **a.** and **b.** and will be called **b'**.
- A commutation relation of type $\frac{f}{j} = \frac{j}{f}$ or $\frac{f}{m} = \frac{m}{f}$ will be called a relation **x.**
- A commutation relation of type $\frac{if}{jf} = \frac{jf}{if}$ will be called relation **y.**

7.2

Definition For $\nu \in G$ we define Y_ν to be the set of $\nu' \in G$ such that there exists a natural number n and a sequence $(\nu_n, \dots, \nu_2, \nu_1)$ satisfying that $\nu_1 = \nu$, $\nu_n = \nu'$ and ν_{i+1} is obtained by applying a relation **y.** to ν_i for all $1 \leq i \leq n-1$.

We say that ν satisfies property (Q) if for all $\nu' \in Y_\nu$ the relations **a.**, **b.**, **b'**, **c.**, **c'**, **d.** or **x.** cannot be applied to ν' . In other words, if $\nu' \in Y_\nu$, there is no generalized left expression in ν' corresponding to relations **a.**, **b.**, **b'**, **c.**, **c'**, **d.** or **x.**.

For $\nu \in G$ we will define $\mathcal{F}_3(\nu)$.

Lemma 7.2 *Let $\nu \in G$. There exists an expression $\mathcal{F}_3(\nu)$, with $\overline{\mathcal{F}_3(\nu)} = \bar{\nu}$, satisfying property (Q).*

Proof.

We start with a definition.

Definition Let $\nu \in G$. If with **y.** relations applied to ν it is possible to apply one of the relations **a.**, **b.**, **b'**, **c.**, **c'**, **d.** or **x.**, we say $\nu \in L$.

If with **y.** relations applied to ν it is possible to apply one of the relations **a.**, **b.**, **b'**, **c.**, **c'**, **d.** or **x.**, we do it and we call $\mathcal{F}_3^1(\nu)$ the resulting expression. This is not well defined because there might be many ways of doing this, but we choose one of these ways arbitrarily. We define recursively $\mathcal{F}_3^n(\nu) = \mathcal{F}_3^1(\mathcal{F}_3^{n-1}(\nu))$.

In the following table the symbol $-$ means that the corresponding relation decreases the corresponding $\nu\{-\}$, the symbol -0 means that sometimes it decreases it and sometimes it maintains it equal and the symbol 0

means it always maintains it equal. By definition $\nu\{\text{positions of } j\text{'s}\} \in \mathbb{N}^k$, $\nu\{\#f\}, \nu\{f \text{ to the right}\}, \nu\{\text{depth } m \text{ and } j\} \in \mathbb{N}$.

	$\nu\{\text{positions of } j\text{'s}\}$	$\nu\{\#f\}$	$\nu\{f \text{ to the right}\}$	$\nu\{\text{depth } m \text{ and } j\}$
c'. $\begin{array}{ccc} s & s & r \\ \underbrace{} & & \\ s & r & s \\ r & s & s \\ & \underbrace{} & \\ & r & s \end{array} = \begin{array}{ccc} s & s & r \\ & \underbrace{} & \\ s & r & \\ \underbrace{} & & \\ r & s & \end{array}$	—

y. $\begin{array}{ccc} if & & jf \\ if & = & if \end{array}$	0	0	0	0

This table shows that there exists some $N \in \mathbb{N}$ such that $\mathcal{F}_3^N(\nu) \notin L$. We put $\mathcal{F}_3(\nu) = \mathcal{F}_3^N(\nu)$, and this proves lemma 7.2 $\square$

7.3

Lemma 7.3 *Let $\nu \in G$. If the k^{th} term of $\mathcal{F}_3(\nu)$ is $^i f$ then the $(k+1)^{th}$ term is $^{i+1} f$ or $^{i+1} j$.*

Proof. Let $\mathcal{F}_3(\nu) = (\omega_k d_k, \dots, \omega_1 d_1)$. We use the following notation : if $a < b$ are two natural numbers, then $[a, b] = \{a, a+1, a+2, \dots, b\}$.

Let $a(1) < b(1) < a(2) < b(2) < \dots < a(r) < b(r)$ be such that

$$\mathcal{F}_3(\nu)[4] = \bigcup_{i=1}^r [a(i), b(i)]$$

Let us fix $1 \leq l \leq r$. We only need to prove

A $d_{b(l)+1} = j, \omega_{b(l)+1} = \omega_{b(l)} + 1$

B For $a_l \leq b(l) - m \leq b_l$ we have $\omega_{b(l)-m} = \omega_{b(l)} - m$.

This means that between the $a(l)^{th}$ term and the $(b(l)+1)^{th}$ term, the picture

looks like this :

We start by proving **A**. Because of the definition of $b(l)$, the $b(l+1)^{th}$ term is a j or m (it can not be an α because $\nu \in G$). Because of the relation **y**. the $b(l)^{th}$ term does not commute with the $b(l+1)^{th}$ term, so we have four possibilities for the $b(l+1)^{th}$ term :

- (1) $\omega_{b(l)} m$ (2) $\omega_{b(l)+1} m$ (3) $\omega_{b(l)-1} j$ (4) $\omega_{b(l)+1} j$

The cases (1), (2) and (3) are impossible respectively by relations **b.**, **b'**. and **c.**, so we have proved **A**.

Now we prove **B** by induction on m . We suppose we have proved it for m , we will prove it for $m+1$. We will use the following picture.

$$a_l \rightarrow$$

$$\begin{array}{cccccccccccccccc}
& & \cdots & \mathbf{x} & \mathbf{x} & \blacksquare & \mathbf{a} & \mathbf{e} & \mathbf{e} & \cdots & \mathbf{e} & \mathbf{c}' & \mathbf{c} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \cdots \\
b_l - m \rightarrow & & & & & & \underbrace{\hspace{1.5cm}} & & & & & & & & & & & \\
& & & & & & & \underbrace{\hspace{1.5cm}} & & & & & & & & & & \\
& & & & & & & & \ddots & & & & & & & & & \\
& & & & & & & & & \underbrace{\hspace{1.5cm}} & & & & & & & \\
& & & & & & & & & & \underbrace{\hspace{1.5cm}} & & & & & & \\
b_l + 1 \rightarrow & & & & & & & & & & & & & & & & & \underbrace{\hspace{1.5cm}}
\end{array}$$

In this picture we have drawn from the $(b_l - m)^{th}$ term to the $(b_l + 1)^{th}$ term. In the $(b_l - m - 1)^{th}$ term we have put some letters, and we will explain what they mean. We put $e = b_l - m - 2$. Let $\omega_e d_e \circ \cdots \circ \omega_1 d_1 : \theta_{s_1} \cdots \theta_{s_n} \rightarrow \theta_{u_1} \cdots \theta_{u_q}$.

Let us say that a letter $\mathbf{n} \in \{\mathbf{x}, \mathbf{a}, \mathbf{e}, \mathbf{c}', \mathbf{c}\}$ is in the place that corresponds to θ_{u_p} . Then if the $(b_l - m - 1)^{th}$ term is ${}^{p-1}f$, by taking this term down in the picture (using relation $\mathbf{y}$ all the times we are allowed), we can use relation $\mathbf{n}$, and by definition of $\mathcal{F}_3(\nu)$, this is not allowed. We conclude that if $\blacksquare$ is in the place that corresponds to θ_{u_i} , then the $(b_l - m - 1)^{th}$ term of $\mathcal{F}_3(\nu)$ is ${}^{i-1}f$, and so we prove **B** and lemma 7.3. $\square$

Lemma 7.3 joint with the properties of $\mathcal{F}_2$ allows us to finish the proof of proposition 7.1. $\square$

8 Elimination of the α 's

We start this section by introducing some relations that will be useful for proving proposition 8.2:

Proposition 8.1 *We have the following equalities :*

$$\mathbf{N1} \quad (\text{id} \otimes f_{r,s}) \circ (f_{r,s} \otimes \text{id}) \circ (\text{id} \otimes \alpha_s) = (\alpha_s \otimes \text{id}) : \theta_r \rightarrow \theta_s \theta_s \theta_r$$

$$\mathbf{N2} \quad (\text{id} \otimes j_s) \circ (f_{sr} \otimes \text{id}) = f_{sr} \circ (j_s \otimes \text{id}) \circ (\text{id} \otimes f_{r,s}) : \theta_s \theta_r \theta_s \rightarrow \theta_r \theta_s$$

$$\mathbf{N3} \quad (\text{id} \otimes f_{r,s}) \circ (f_{r,s} \otimes \text{id}) \circ (\text{id} \otimes p_s) = (p_s \otimes \text{id}) \circ f_{r,s} : \theta_r \theta_s \rightarrow \theta_s \theta_s \theta_r$$

$$\mathbf{N4} \quad f_{r,s} \circ (\text{id} \otimes \epsilon_s) = \epsilon_s \otimes \text{id} : \theta_r \rightarrow \theta_s \theta_r$$

$$\mathbf{N5} \quad (m_r \otimes \text{id}) \circ p_r = (\text{id} \otimes m_r) \circ p_r = \text{id} \quad \begin{array}{c} r \\ \underbrace{\quad} \\ x \quad r \\ r \end{array} = \begin{array}{c} r \\ \underbrace{\quad} \\ r \quad x \\ r \end{array} = \begin{array}{c} r \end{array}$$

$$\mathbf{N6} \quad j_r \circ (\text{id} \otimes \epsilon_r) = j_r \circ (\epsilon_r \otimes \text{id}) = \text{id} \quad \begin{array}{c} r \\ \underbrace{\quad} \\ r \quad \hat{r} \\ r \end{array} = \begin{array}{c} r \\ \underbrace{\quad} \\ \hat{r} \quad r \\ r \end{array} = \begin{array}{c} r \end{array}$$

$$\mathbf{N7} \quad (\text{id} \otimes j_r) \circ (p_r \otimes \text{id}) = \begin{array}{c} r \quad r \\ \underbrace{\quad} \\ r \quad r \quad r \\ r \quad r \end{array} = \begin{array}{c} r \quad r \\ \underbrace{\quad} \\ r \quad r \quad r \\ r \quad r \end{array} = \begin{array}{c} r \quad r \\ \underbrace{\quad} \\ r \\ r \quad r \end{array}$$

$$= (j_r \otimes \text{id}) \circ (\text{id} \otimes p_r) = p_r \circ j_r$$

Proof. We will give in order the relations needed to prove each one of this equations (CR means commutation relations) :

- **N1** : **e**, **a**
- **N2** : **c'**, **a**
- **N3** : **e**, **N2**, CR, **a**
- **N4** : CR, **e**, **a'**
- **N5** : 2, 3
- **N6** : CR, 2, 3
- **N7** : 2, CR, 2, 5, CR

□

Proposition 8.2 *Let $\tau = \overline{g \circ \xi}$ with $g \in G$, $\xi =^i \alpha_s$. There exists a set Π and for each $\pi \in \Pi$ a polynomial λ_π and $g_\pi \in G$ such that*

$$\tau = \overline{\sum_{\pi \in \Pi} \lambda_\pi g_\pi}$$

Proof.

We start with a lemma

Lemma 8.3 *For proving proposition 8.2 it suffices to prove it for $\xi =^i p_s$ and $\xi =^i \epsilon_s$.*

Proof. We have that $\mu_1 = (\mathcal{F}_3(g),^i \alpha_s)$ is an expression of the morphism τ . With commutation relations we change μ_1 in μ_2 , an expression where the α is as far as possible to the left (in the picture is in the lowest place possible). Let us say that in μ_2 we have that ${}^p \alpha_s$ is the k^{th} term. We have seven possibilities for the $(k+1)^{th}$ term : (1) ${}^{p-1}j$, (2) ${}^p j$, (3) ${}^{p+1}j$, (4) ${}^p m$, (5) ${}^{p+1}m$, (6) ${}^{p+1}f$ and (7) ${}^{p-1}f$.

- In the case (1), by relation 2 we are in the case $\xi =^p p_s$.
- In the case (2), by relation 6 we find that $\tau = 0$.
- In the case (3) by definition of p_s we are in the case $\xi =^p p_s$.
- In the case (4) by relation 1 we are in the case $\xi =^p \epsilon_s$.
- In the case (5) by definition of ϵ_s we are in the case $\xi =^p \epsilon_s$.
- In the case (6), by remark 7 we have that there exists c such that the $(k+r)^{th}$ term is ${}^{p+r}f$ for every $0 \leq r < c$ and ${}^{p+c}j$ for $r = c$. But with the relation **N2** we can easily verify the following equality by induction :

$${}^{p+c}j \circ {}^{p+c-1}f \circ \dots \circ {}^{p+1}f = ({}^{p+c-1}f \circ {}^{p+c-2}f \circ \dots \circ {}^{p+1}f) \circ {}^{p+1}j \circ ({}^{p+2}f \circ {}^{p+2}f \circ \dots \circ {}^{p+c}f)$$

So if we replace the left hand side of this equation by its right hand side we can take the α more to the left, and we find a new expression of $\tau : (g_1, {}^{p+1}j, {}^p \alpha, g_2)$, with $g_1, g_2 \in G$ and by the definition of p_s we get to the case $\xi =^p p_s$.

- In the case (7), by the remark 7 we have that the $(k+2)^{th}$ term is ${}^p f$. So if we apply relation **N1** we arrive to a new expression μ_3 of $\tau : \mu_3 = (g_1, {}^{p-1} \alpha_s, g_2)$, $g_1, g_2 \in G$, where g_1 is a good g -expression, the α is still in the k^{th} term and μ_3 has strictly less terms than μ_2 . Now we repeat the process of taking in μ_3 the α as far to the left as possible and if we arrive another time to the case (7), we find a corresponding μ_4 . If we repeat this process enough times, finally we will arrive to one of the other 6 cases. This finishes the proof of the lemma.

□

Proof of the proposition 8.2 for $\xi =^i p_s$. The proof of this case is very similar to the proof of lemma 8.3, but we use different relations. We have that $\mu_1 = (\mathcal{F}_3(g), \dot{p}_s)$ is an expression of the morphism τ . With commutation relations we change μ_1 in μ_2 , an expression where the p is as far to the left as possible. Let us say that in μ_2 we have that the k^{th} term is $^p p_s$. We have seven possibilities for the $(k+1)^{th}$ term : (1) ^{p-1}j , (2) $^p j$, (3) ^{p+1}j , (4) $^p m$, (5) ^{p+1}m , (6) ^{p+1}f and (7) ^{p-1}f .

- In the cases (1) and (3) we use relation **N7**, and we have that the p is more to the left than before.
- In the case (2) we have that $\tau = 0$ because the relations 5 and 6 tells us that $j_s \circ p_s = 0$.
- In the cases (4) and (5) we use relation **N5** and we find an expression of τ that is in G .
- In the case (6), by a similar argument to that of case (6) of lemma 8.3, we go back to case (3).
- In the case (7) by a similar argument to that of case (7) of lemma 8.3, but using the relation **N3** instead of relation **N1** we see that, as in the cases (1), (3) and (6), the p is more to the left than before. So if we repeat enough times we will go back to one of the cases that are left, this means, cases (2), (4) or (5).

Proof of the proposition 8.2 for $\xi =^i \epsilon_s$. We have that $\mu_1 = \mathcal{F}_3(g) \circ^i \epsilon_s$ is an expression of morphism τ . With commutation relations we change μ_1 in μ_2 , an expression where the ϵ is as far to the left as possible. Let us say that in μ_2 we have that the k^{th} term is $^p \epsilon_s$. We have five possibilities for the $(k+1)^{th}$ term : (1) ^{p-1}j , (2) $^p j$, (3) $^p m$, (4) $^p f$ and (5) ^{p-1}f .

- In the cases (1) and (2), using relation **N6** we find an expression of τ that is in G .
- In the case (4), by a similar argument to that of the case (6) in lemma 8.3, we go back to case (2).

- In the case (5), by a similar argument to that of the case (7) in lemma 8.3, but using relation **N4** instead of relation **N1** we see that the ϵ is more to the left than before. So, if we repeat enough times we will go back to one of the cases that are left.
- Case (3) is treated in section 6.0.1.

□

By using proposition 8.2 repeatedly we have the following

Corollary 8.4 *Let ν be an R -expression. There exists a set Π and for each $\pi \in \Pi$ a polynomial λ_π and $g_\pi \in G$ such that*

$$\bar{\nu} = \overline{\sum_{\pi \in \Pi} \lambda_\pi g_\pi}$$

9 Good order

The purpose of this section is to change a good g -expression into a good g -expression in good order.

Proposition 9.1 *Let $t > t'$ and $\alpha, \beta \in \{m, ch, cch\}$. There exists u and u' such that $\alpha(t) \circ \beta(t') = \beta(u') \circ \alpha(u)$.*

Proof.

- Let us consider the case $\beta = ch$ or cch and $\alpha = m$. We have two possible cases. In the first one $m(t)$ commutes with $\beta(t')$, and in the second one they do not commute, so we use commutation relations and relation **b**.

- $m(t) \circ \beta(t') = \beta(t') \circ m(t+1)$

- $m(t) \circ \beta(t') = \beta(t') \circ m(t)$

- The case $i = 1, 2$ or 3 and $k = 1$ is easy because $\alpha(t)$ commutes with $m(t')$.

- The last case is $i = 2$ or 3 and $k = 2$ or 3 . We will only treat the case $i = 2, k = 2$, the other ones are similar. We will prove that $\text{ch}(t) \circ \text{ch}(t') = \text{ch}(t') \circ \text{ch}(t)$. For this we need two preliminary lemmas.

Lemma 9.2 *If $f = {}^{i_q} f \circ \dots \circ {}^{i_1} f$, $g = {}^{k_p} f \circ \dots \circ {}^{i_1} f \in \text{Hom}(\theta_{s_1} \dots \theta_{s_n}, \theta_{u_1} \dots \theta_{u_l})$, then $f = g$.*

Proof. Relations **a.** and **d.** are exactly the relations defining the symmetric group. $\square$

Lemma 9.3 *The following expressions represent the same morphism : $(j^i, f^{i-2}, f^{i-1}, f^i)$ and (f^i, f^{i+1}, j^{i+1}) .*

Proof. In the following chain of relations we apply respectively commutation relations, relation **c.** and relation **a.** :

$\square$

Now we are able to finish the case $i = k = 2$. In the following chain of equalities we apply respectively commutation relations to take an j down, then lemma 9.2 for reordering a composition of f 's, and finally with commutation relations we take up an j and apply lemma 9.3 :

Definition If ν is a good g -expression we will name $\mathcal{F}_4(\nu)$ the good g -expression in the good order such that $\overline{\mathcal{F}_4(\nu)} = \overline{\nu}$

10 Conclusion of the proof of theorem 3.1

10.1

Definition If $\tau = \sum_i g_i \lambda_i$, with I a finite set, λ_i polynomials and $g_i \in G$, we define $\mathcal{F}_3(\tau) = \sum_i \mathcal{F}_3(g_i) \lambda_i$ and $\mathcal{F}_4(\tau) = \sum_i \mathcal{F}_4(g_i) \lambda_i$.

Definition Let $\nu \in G$. We define $\mathcal{F}_5^1(\nu) = \mathcal{F}_4\mathcal{F}_3\mathcal{F}_2(\nu)$. This is well defined, because $\mathcal{F}_2(\nu)$ is a linear combination of elements of G and $\mathcal{F}_3(\nu')$ is a good g -expression.

We define inductively $\mathcal{F}_5^n(\nu)$: If $\mathcal{F}_5^n(\nu)\{\#m - \text{bad}\} \neq 0$ we define $\mathcal{F}_5^{n+1}(\nu) = \mathcal{F}_5^1\mathcal{F}_5^n(\nu)$ and if $\mathcal{F}_5^n(\nu)\{\#m - \text{bad}\} = 0$, we define $\mathcal{F}_5^{n+1}(\nu) = \mathcal{F}_5^n(\nu)$.

Proposition 10.1 $\mathcal{F}_5^n(\nu)$ stabilizes for n large.

Proof. Let us suppose it doesn't stabilize. This means that for all $n \in \mathbb{N}$, we have $\mathcal{F}_5^n(\nu)\{\#m - \text{bad}\} \neq 0$. So we apply infinitely many times relation 7 in this process. When we apply relation 7 to an expression we obtain a

sum of three expressions, the first one is $\frac{x}{r} \frac{r}{r}$, the second one $\frac{\overbrace{r \ r}}{r}$, and

the third one is $\frac{\overbrace{r \ r}}{\diamond r}$. In this three expressions relation 7 always decreases

strictly $\nu\{m, j \text{ equal to left}\} \in \mathbb{N}$ and the other relations used in $\mathcal{F}_2$, $\mathcal{F}_3$ and $\mathcal{F}_4$ don't change $\nu\{m, j \text{ equal to left}\}$. To see this, we make a brief review of all relations used in defining $\mathcal{F}_2$, $\mathcal{F}_3$ and $\mathcal{F}_4$:

- $\mathcal{F}_2$: commutation relations, **a.** in the opposite sense, 7, **g**, **f**
- $\mathcal{F}_3$: **a.**, **b.**, **b'.**, **c.**, **c'.**, **d.**, **x.**, **y.**
- $\mathcal{F}_4$: commutation relations, **a.**, **b.**, **c.**, **d.**

So we have a contradiction, which allows us to conclude the proof. $\square$

Remark As $\mathcal{F}_4(\nu)$ is a good g -expression in the good order, $\mathcal{F}_5(\nu)$ is a good g -expression in the good order satisfying $\mathcal{F}_5(\nu)\{\#m - \text{bad}\} = 0$.

10.2

We start by a useful reformulation of proposition 2.2 in our terminology:

Corollary 10.2 *Let $(W, \mathcal{S})$ be a right-angled Coxeter system. Let $(s_1, \dots, s_n) \in \mathcal{S}^n$. We have the equality of sets :*

$FL(s_1, \dots, s_n) = \{\nu \text{ good } g\text{-expressions in } \text{Hom}(\theta_{s_1} \cdots \theta_{s_n}, R) \text{ in good order,}$

$$\text{with } \nu\{\#m\text{-bad}\} = \nu\{\#j\text{-bad}\} = 0\}$$

In section 3.3 we showed that in order to prove Theorem 3.1 we only need to prove the following proposition :

Proposition 10.3 *Let $(s_1, \dots, s_n) \in \mathcal{S}^n$. If $f \in \text{Hom}(\theta_{s_1} \cdots \theta_{s_n}, R)$ then there exists I a finite set and for $i \in I$, $a_i \in FL(s_1, \dots, s_n)$ and λ_i polynomials such that $f = \sum_i a_i \lambda_i$.*

As f is a linear combination over A of R -expressions, we can restrict our attention to the case where f is an R -expression. By corollary 8.4 we can restrict to the case $f \in G$. By proposition 10.1 and remark 10.1 we can restrict to the case where f is a good g -expression in the good order and with $\nu\{\#m\text{-bad}\} = 0$. So, the following lemma allows us to conclude the proof of Theorem 3.1 :

Lemma 10.4 *If ν is a good R -expression in the good order and $\nu\{\#m\text{-bad}\} = 0$, then $\nu\{\#j\text{-bad}\} = 0$.*

Proof. Suppose $\nu\{\#j\text{-bad}\} \neq 0$. Let us put $k = \nu\{\max. j\text{-bad}\}$. Let ${}^z j_s$ be the k^{th} term of ν . The $(k+1)^{\text{th}}$ term of ν can not be ${}^z m_s$, because $\nu\{\#m\text{-bad}\} = 0$.

Let us define by induction the natural number N_p for $r \geq p \geq 1$ (where r will be defined in the process). We define $N_1 = z + 1$. Let us suppose that we have defined N_p .

- If the $(k+p)^{\text{th}}$ term of ν is ${}^i m$, then $N_{p+1} = N_p$.
- Suppose that the $(k+p)^{\text{th}}$ term of ν is ${}^i j$. If $i > N_p - 1$ then $N_{p+1} = N_p$ and if $i = N_p - 1$ then $r = p$.
- Suppose that the $(k+p)^{\text{th}}$ term of ν is ${}^i f$. If $i \notin \{N_p - 1, N_p - 2\}$ then $N_{p+1} = N_p$. If $i = N_{p-1}$ then $N_{p+1} = N_p + 1$ and if $i = N_{p-2}$ then $N_{p+1} = N_p - 1$.

The fact that ν is a good R -expression in the good order allows us to conclude that N_p is well defined. By construction, the N_p^{th} element of $\hat{\nu}_{k+p}$ is always the same element of $\mathcal{S}$, it is of left type, and it is evident that r is a finite number. This contradicts the definition of $\nu\{\max. j - \text{bad}\}$, so we have a contradiction. We conclude that $\nu\{\#j - \text{bad}\} = 0$. $\square$
